# Virtual Physics <br> Equation-Based Modeling 

TUM, October 28, 2014

## Compiling Modelica

Dr. Dirk Zimmer

## Compiling of Modelica

- In this lecture, we are going to investigate the compilation process of a Modelica model.

- The compilation can be roughly partitioned in 5 stages:
- Parsing
- Preprocessing
- Flattening
- Transformation into State-Space Form
- Code Generation

## Parsing

- The grammar of Modelica is specified as EBNF in the language definition.
- Modelica is not a LL(1)-language, so Parsing involves a few difficulties.
- Still, the language is rather easy to parse and no special means are required.
- Preprocessing applies the means of type generation.
- Essentially, this concerns the extends clause and a few other language means that we do not know yet.
- Implementing the extension is not trivial, since an extension of a package may generate new type names. Hence the lookup of classes and the extension may happen in several interleaved steps.
- Another difficulty is that the inherited elements also inherit the namespace.

## Flattening

- Flattening means that the hierarchical model structure is destroyed and that all parameters, variables and equations are collected in one global set.
- Also the connections are transformed into equations.
- Function definitions are typically not flattened.
- The flattened model then represents a (potentially very large) systems of DAEs.

## Flattening

```
model Circuit
    Resistor R1(R=100);
    Resistor R2(R=20);
    Capacitor C(C=1e-6);
    Inductor L(L=0.0015;
    Ground G;
```

```
equations
```

equations
connect(G.p,S.n)
connect(G.p,S.n)
connect(G.p,L.n)
connect(G.p,L.n)
connect(G.p,R2.n)
connect(G.p,R2.n)
connect(G.p,C.n)
connect(G.p,C.n)
connect(S.p,R1.p)
connect(S.p,R1.p)
connect(S.p,L.p)
connect(S.p,L.p)
connect(R1.n,R2.p)
connect(R1.n,R2.p)
connect(R1.n,C.p)

```
    connect(R1.n,C.p)
```

    SineVSource S(Ampl=15, Freq=50);
    
## model Circuit

```
    parameter Real R1.R = 100;
```

    parameter Real R2.R = 20;
    ...
    Real R1.v; Real R1.i; Real R1.p.v;
    Real R1.p.i; Real R1.n.v; Real R1.n.i;
    Real R2.v; Real R2.i; ...
    equations
R1.v = R1.R*R1.i;
R1.v = R1.p.v - R1.n.v;
0 = R1.p.i + R1.n.i;
R1.i = R1.p.i;
R2.v = R2.R*R2.i;
...
G.p.v = S.n.v;
G.p.v = L.n.v;
G.p.v = R2.n;
G.p.i + S.n.i + L.n.i + R2.n.i + C.n.i
= 0;
...
end Pin;

## Into State-Space Form

- A system of DAEs can typically be represented in the following implicit form:

$$
\mathbf{0}=\mathrm{F}(\mathrm{~d} \mathbf{x} / \mathrm{d} t, \mathbf{x}, \mathbf{u}, t)
$$

- The goal is, to transform this form into the explicit state-space form that is suited for numerical ODE solvers.

$$
\mathrm{d} \mathbf{x} / \mathrm{d} t=\mathrm{f}(\mathbf{x}, \mathbf{u}, t)
$$

- This transformation is also called Index-Reduction.
- An efficient index-reduction is the heart of any Modelica Compiler and its realization defines the remaining content of this lecture.

## Example

Let us review the simple electric circuit from lecture 2.

## Flat System of DAEs

If we flatten this system, we know that 16 equations result:

$$
\begin{array}{cc}
v_{\mathrm{G}}=0 \\
\mathrm{v}_{\mathrm{S} 2}=\mathrm{v}_{\mathrm{R} 1} & \mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{S} 2}=0 \\
\mathrm{i}_{\mathrm{S} 2}+\mathrm{i}_{\mathrm{R} 1}=0 & \mathrm{v}_{\mathrm{S} 1}+10 \mathrm{~V}=\mathrm{v}_{\mathrm{S} 2} \\
\mathrm{v}_{\mathrm{R} 2}=\mathrm{v}_{\mathrm{C} 1} & \mathrm{u}_{\mathrm{R}}=\mathrm{R} \cdot \mathrm{i}_{\mathrm{R} 1} \\
\mathrm{i}_{\mathrm{R} 2}+\mathrm{i}_{\mathrm{C} 1}=0 & \mathrm{I}_{\mathrm{R} 1}+\mathrm{I}_{\mathrm{R} 2}=0 \\
\mathrm{v}_{\mathrm{C} 2}=\mathrm{v}_{\mathrm{G}} & \mathrm{v}_{\mathrm{R} 1}+\mathrm{u}_{\mathrm{R}}=\mathrm{v}_{\mathrm{R} 2} \\
\mathrm{v}_{\mathrm{S} 1}=\mathrm{v}_{\mathrm{G}} & \mathrm{C} \cdot \mathrm{du}_{\mathrm{C}} / \mathrm{d} t=\mathrm{i}_{\mathrm{C} 1} \\
\mathrm{i}_{\mathrm{C} 2}+\mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{G}}=0 & \mathrm{I}_{\mathrm{C} 1}+\mathrm{I}_{\mathrm{C} 2}=0 \\
& \mathrm{v}_{\mathrm{C} 1}+\mathrm{u}_{\mathrm{C}}=\mathrm{v}_{\mathrm{C} 2}
\end{array}
$$

Node equations
Component Equations

## Removing Alias Variables

The first thing we can do, is to eliminate the trivial equations by removing "alias" variables.

$$
\begin{array}{cc}
\mathrm{v}_{\mathrm{G}}=0 \\
\mathrm{v}_{\mathrm{S} 2}=\mathrm{v}_{\mathrm{R} 1} & \mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{S} 2}=0 \\
\mathrm{i}_{\mathrm{S} 2}+\mathrm{i}_{\mathrm{R} 1}=0 & \mathrm{v}_{\mathrm{S} 1}+10 \mathrm{~V}=\mathrm{v}_{\mathrm{S} 2} \\
\mathrm{v}_{\mathrm{R} 2}=\mathrm{v}_{\mathrm{C} 1} & \mathrm{u}_{\mathrm{R}}=\mathrm{R} \cdot \mathrm{i}_{\mathrm{R} 1} \\
\mathrm{i}_{\mathrm{R} 2}+\mathrm{i}_{\mathrm{C} 1}=0 & \mathrm{I}_{\mathrm{R} 1}+\mathrm{I}_{\mathrm{R} 2}=0 \\
\mathrm{v}_{\mathrm{C} 2}=\mathrm{v}_{\mathrm{G}} & \mathrm{v}_{\mathrm{R} 1}+\mathrm{u}_{\mathrm{R}}=\mathrm{v}_{\mathrm{R} 2} \\
\mathrm{v}_{\mathrm{S} 1}=\mathrm{v}_{\mathrm{G}} & \mathrm{C} \cdot \mathrm{du} / \mathrm{d} t=\mathrm{i}_{\mathrm{C} 1} \\
\mathrm{i}_{\mathrm{C} 2}+\mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{G}}=0 & \mathrm{I}_{\mathrm{C} 1}+\mathrm{I}_{\mathrm{C} 2}=0 \\
& \mathrm{v}_{\mathrm{C} 1}+\mathrm{u}_{\mathrm{C}}=\mathrm{v}_{\mathrm{C} 2}
\end{array}
$$

Node equations
Component Equations

## Removing Alias Variables

The first thing we can do, is to eliminate the trivial equations by removing "alias" variables.

$$
\begin{aligned}
& \mathrm{V}_{\mathrm{G}}=0 \\
& \begin{array}{c}
\mathrm{i}_{\mathrm{S} 2}+\mathrm{i}_{\mathrm{R} 1}=0
\end{array} \\
& V_{R 2}=V_{C 1} \\
& \mathrm{i}_{\mathrm{R} 2}+\mathrm{i}_{\mathrm{C} 1}=0 \\
& V_{C_{2}}=V_{G} \\
& V_{S 1}=V_{G} \\
& \mathrm{i}_{\mathrm{C} 2}+\mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{G}}=0 \\
& \mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{S} 2}=0 \\
& \mathrm{v}_{\mathrm{G}}+10 \mathrm{~V}=\mathrm{v}_{\mathrm{R} 1} \\
& \mathrm{u}_{\mathrm{R}}=\mathrm{R} \cdot \mathrm{i}_{\mathrm{R} 1} \\
& I_{R 1}+I_{R 2}=0 \\
& v_{R 1}+u_{R}=v_{C 1} \\
& \mathrm{C} \cdot \mathrm{du}_{\mathrm{C}} / \mathrm{d} t=\mathrm{i}_{\mathrm{C} 1} \\
& I_{C 1}+I_{C 2}=0 \\
& \mathrm{v}_{\mathrm{C} 1}+\mathrm{u}_{\mathrm{C}}=\mathrm{v}_{\mathrm{G}}
\end{aligned}
$$

Node equations
Component Equations

## Removing Alias Variables

The first thing we can do, is to eliminate the trivial equations by removing "alias" variables.

$$
\begin{array}{cc} 
& v_{G}=0 \\
\frac{v_{S 2}}{}=v_{R 1} & i_{S 1}+i_{S 2}=0 \\
-i_{S 1}+i_{R 1}=0 & v_{G}+10 \mathrm{~V}=v_{R 1} \\
\hdashline v_{R 2}=v_{C 1} & u_{R}=R \cdot i_{R 1} \\
-i_{R 1}+i_{C 1}=0 & t_{R 1}+i_{R 2}=0 \\
v_{C 2}=v_{G} & v_{R 1}+u_{R}=v_{C 1} \\
\hline-\mathrm{v}_{S 1}=v_{G} & C \cdot d u_{C} / d t=i_{C 1} \\
-i_{C 1}+i_{S 1}+i_{G}=0 & \frac{1}{C 1}+l_{C 2}=0 \\
& v_{C 1}+u_{C}=v_{G}
\end{array}
$$

Node equations
Component Equations

## Removing Alias Variables

In total there remain 9 equations with 9 variables. (actually we could reduce even further...)

$$
\begin{gathered}
v_{G}=0 \\
v_{G}+10 \mathrm{~V}=\mathrm{v}_{\mathrm{R} 1} \\
\mathrm{u}_{\mathrm{R}}=\mathrm{R} \cdot \mathrm{i}_{\mathrm{R} 1} \\
\mathrm{v}_{\mathrm{R} 1}+\mathrm{u}_{\mathrm{R}}=\mathrm{v}_{\mathrm{C} 1} \\
\mathrm{C} \cdot \mathrm{du}_{\mathrm{C}} / \mathrm{d} t=\mathrm{i}_{\mathrm{C} 1} \\
\mathrm{v}_{\mathrm{C} 1}+\mathrm{u}_{\mathrm{C}}=\mathrm{v}_{\mathrm{G}} \\
-\mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{R} 1}=0 \\
-\mathrm{i}_{\mathrm{R} 1}+\mathrm{i}_{\mathrm{C} 1}=0 \\
-\mathrm{i}_{\mathrm{C} 1}+\mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{G}}=0
\end{gathered}
$$

## Into State Space Form

We now want to transform this set into a computable state-space form.

- Input Variables: $\mathbf{u}=()$
- State Variables: $\mathbf{x}=\left(u_{c}\right)$
- State Derivatives: $\mathrm{dx} / \mathrm{d} t=\left(\mathrm{d} \mathrm{u}_{\mathrm{c}} / \mathrm{d} t\right)$
- Output Variables: $\mathbf{y}=()$
- Since $\mathbf{u}$ and $\mathbf{y}$ are empty, the system only consists in the A-matrix.
(Remember the state-space form of lecture 1)

## Non-causal set:

$$
\begin{aligned}
& \mathrm{v}_{\mathrm{G}}=0 \\
& \mathrm{v}_{\mathrm{G}}+10 \mathrm{~V}=\mathrm{v}_{\mathrm{R} 1} \\
& \mathrm{u}_{\mathrm{R}}=\mathrm{R} \cdot \mathrm{i}_{\mathrm{R} 1} \\
& \mathrm{v}_{\mathrm{R} 1}+\mathrm{u}_{\mathrm{R}}=\mathrm{v}_{\mathrm{C} 1} \\
& \mathrm{C} \cdot \mathrm{du}_{\mathrm{C}} / \mathrm{d} t=\mathrm{i}_{\mathrm{C} 1} \\
& \mathrm{v}_{\mathrm{C} 1}+\mathrm{u}_{\mathrm{C}}=\mathrm{v}_{\mathrm{G}} \\
& -\mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{R} 1}=0 \\
& -\mathrm{i}_{\mathrm{R} 1}+\mathrm{i}_{\mathrm{C} 1}=0 \\
& -\mathrm{i}_{\mathrm{C} 1}+\mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{G}}=0
\end{aligned}
$$

## Forward Causalization

In order to generate computable code, we must causalize the equations.

- Causalizing means that we determine which unknown shall be determined by which equation.
- We start with those equations that have only one unknown.
- These can be causalized immediately
- The state (here: $\mathbf{u}_{\mathrm{c}}$ ) is assumed to be known.

## Non-causal set:

$$
\begin{aligned}
& \mathrm{v}_{\mathrm{G}}=0 \\
& \mathrm{v}_{\mathrm{G}}+10 \mathrm{~V}=\mathrm{v}_{\mathrm{R} 1} \\
& \mathrm{u}_{\mathrm{R}}=\mathrm{R} \cdot \mathrm{i}_{\mathrm{R} 1} \\
& \mathrm{v}_{\mathrm{R} 1}+\mathrm{u}_{\mathrm{R}}=\mathrm{v}_{\mathrm{C} 1} \\
& \mathrm{C} \cdot \mathrm{~d} \mathrm{u}_{\mathrm{C}} / \mathrm{d} t=\mathrm{i}_{\mathrm{C} 1} \\
& \mathrm{v}_{\mathrm{C} 1}+\mathrm{u}_{\mathrm{C}}=\mathrm{v}_{\mathrm{G}} \\
& -\mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{R} 1}=0 \\
& -\mathrm{i}_{\mathrm{R} 1}+\mathrm{i}_{\mathrm{C} 1}=0 \\
& -\mathrm{i}_{\mathrm{C} 1}+\mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{G}}=0
\end{aligned}
$$

## Forward Causalization

In order to generate computable code, we must causalize the equations.

- Causalizing means that we determine which unknown shall be determined by which equation.
- We start with those equations that have only one unknown.
- These can be causalized immediately
- The state (here: $\mathbf{u}_{\mathrm{c}}$ ) is assumed to be known.

## Non-causal Set:

$$
\begin{aligned}
& \mathrm{v}_{\mathrm{G}}+10 \mathrm{~V}=\mathrm{v}_{\mathrm{R} 1} \\
& \mathrm{u}_{\mathrm{R}}=\mathrm{R} \cdot \mathrm{i}_{\mathrm{R} 1} \\
& \mathrm{v}_{\mathrm{R} 1}+\mathrm{u}_{\mathrm{R}}=\mathrm{v}_{\mathrm{C} 1} \\
& \mathrm{C} \cdot \mathrm{~d} \mathrm{u}_{\mathrm{C}} / \mathrm{d} t=\mathrm{i}_{\mathrm{C} 1} \\
& \mathrm{v}_{\mathrm{C} 1}+\mathrm{u}_{\mathrm{C}}=\mathrm{v}_{\mathrm{G}} \\
& -\mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{R} 1}=0 \\
& -\mathrm{i}_{\mathrm{R} 1}+\mathrm{i}_{\mathrm{C} 1}=0 \\
& -\mathrm{i}_{\mathrm{C} 1}+\mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{G}}=0
\end{aligned}
$$

## Causal List:

& \mathrm{i}_{\mathrm{C} 1}:=\mathrm{i}_{\mathrm{R} 1}
\end{aligned}
$$

## Causality Graph

Robotics and Mechatronics Centre

- We can represent the causalized system by means of an acyclic directed graph: The causality graph.
- The vertices of the graph are the equations or assignments
- The edges point out the computational dependence.
- The causality graph gives rise to a partial order of its vertices (equations)

## Causal List:

$$
\begin{aligned}
& \mathrm{v}_{\mathrm{G}}:=0 \\
& \mathrm{v}_{\mathrm{C} 1}:=-\mathrm{u}_{\mathrm{C}}+\mathrm{v}_{\mathrm{G}} \\
& \mathrm{v}_{\mathrm{R} 1}:=\mathrm{v}_{\mathrm{G}}+10 \mathrm{~V} \\
& \mathrm{u}_{\mathrm{R}}:=\mathrm{v}_{\mathrm{C} 1}-\mathrm{v}_{\mathrm{R} 1} \\
& \mathrm{i}_{\mathrm{R} 1}:=\mathrm{u}_{\mathrm{R}} / \mathrm{R} \\
& \mathrm{i}_{\mathrm{S} 1}:=\mathrm{i}_{\mathrm{R} 1} \\
& \mathrm{i}_{\mathrm{C} 1}:=\mathrm{i}_{\mathrm{R} 1} \\
& \frac{\mathrm{~d} \mathrm{u}_{\mathrm{c}}}{} \mathrm{~d} t:=\mathrm{i}_{\mathrm{c}} / \mathrm{C} \\
& \mathrm{i}_{\mathrm{G}}:=\mathrm{i}_{\mathrm{C} 1}-\mathrm{i}_{\mathrm{S} 1}
\end{aligned}
$$

- We can represent the causalized system by means of an acyclic directed graph: The causality graph.

Causal List:

$$
\begin{aligned}
& \mathrm{v}_{\mathrm{G}}:=0 \\
& \mathrm{v}_{\mathrm{C} 1}:=-\mathrm{u}_{\mathrm{C}}+\mathrm{v}_{\mathrm{G}} \\
& \mathrm{v}_{\mathrm{R} 1}:=\mathrm{v}_{\mathrm{G}}+10 \mathrm{~V} \\
& \mathrm{u}_{\mathrm{R}}:=\mathrm{v}_{\mathrm{C} 1}-\mathrm{v}_{\mathrm{R} 1} \\
& \mathrm{i}_{\mathrm{R} 1}:=\mathrm{u}_{\mathrm{R}} / \mathrm{R} \\
& \mathrm{i}_{\mathrm{S} 1}:=\mathrm{i}_{\mathrm{R} 1} \\
& \mathrm{i}_{\mathrm{C} 1}:=\mathrm{i}_{\mathrm{R} 1} \\
& \underline{\mathrm{du}_{\underline{c}}} / \mathrm{d} t:=\mathrm{i}_{\underline{\mathrm{c} 1}} / \mathrm{C} \\
& \mathrm{i}_{\mathrm{G}}:=\mathrm{i}_{\mathrm{C} 1}-\mathrm{i}_{\mathrm{S} 1}
\end{aligned}
$$

## Structure Incidence Matrix

- The non-causal set of equations can be represented by a structural incidence matrix.
- The row vector corresponds to the set of equations
- The column vector represents the set of unknowns.

## Non-causal set:

$$
\begin{aligned}
& \mathrm{v}_{\mathrm{G}}=0 \\
& \mathrm{v}_{\mathrm{G}}+10 \mathrm{~V}=\mathrm{v}_{\mathrm{R} 1} \\
& \mathrm{u}_{\mathrm{R}}=\mathrm{R} \cdot \mathrm{i}_{\mathrm{R} 1} \\
& \mathrm{v}_{\mathrm{R} 1}+\mathrm{u}_{\mathrm{R}}=\mathrm{v}_{\mathrm{C} 1} \\
& \mathrm{C} \cdot \mathrm{~d} \mathrm{u}_{\mathrm{C}} / \mathrm{d} t=\mathrm{i}_{\mathrm{C} 1} \\
& \mathrm{v}_{\mathrm{C} 1}+\mathrm{u}_{\mathrm{C}}=\mathrm{v}_{\mathrm{G}} \\
& -\mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{R} 1}=0 \\
& -\mathrm{i}_{\mathrm{R} 1}+\mathrm{i}_{\mathrm{C} 1}=0 \\
& -\mathrm{i}_{\mathrm{C} 1}+\mathrm{i}_{\mathrm{S} 1}+\mathrm{i}_{\mathrm{G}}=0
\end{aligned}
$$

## Structure Incidence Matrix

9) $-i_{C 1}+i_{S 1}+i_{G}=0$

## Structure Incidence Matrix

- If we permute the sets of equations and variables given an order that is induced by the causality graph...
- ...the structural incidence matrix has a lower triangular form with a full diagonal.

## Causal List:

1) $v_{G}:=0$
2) $v_{C 1}:=-u_{C}+v_{G}$
3) $v_{R 1}:=v_{G}+10 \mathrm{~V}$
4) $u_{R}:=v_{C 1}-v_{R 1}$
5) $i_{R 1}:=u_{R} / R$
6) $i_{S 1}:=i_{R 1}$
7) $i_{C 1}:=i_{R 1}$
8) $d u_{C} / d t:=i_{c 1} / C$
9) $i_{G}:=i_{C 1}-i_{S 1}$

## Structure Incidence Matrix

## Causal List:

|  | $\mathrm{v}_{6}$ | $\mathrm{v}_{\mathrm{c} 1}$ | $\mathrm{V}_{\mathrm{R} 1}$ | $u_{R}$ | $\mathrm{i}_{\mathrm{R} 1}$ | $\mathrm{i}_{51}$ | $\mathrm{i}_{\mathrm{c} 1}$ | duc | $\mathrm{i}_{6}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1) | x |  |  |  |  |  |  |  |  |
| 6) | x | x |  |  |  |  |  |  |  |
| 2) | x |  | x |  |  |  |  |  |  |
| 4) |  | x | X | x |  |  |  |  |  |

2) $v_{C 1}:=-u_{C}+v_{G}$
3) $v_{R 1}:=v_{G}+10 V$
4) $u_{R}:=v_{C 1}-v_{R 1}$
5) $i_{R 1}:=u_{R} / R$
6) $i_{S 1}:=i_{R 1}$
7) $i_{C 1}:=i_{R 1}$
8) $d u_{C} / d t:=i_{c 1} / C$
9) $i_{G}:=i_{C 1}-i_{S 1}$

## Lower Triangular Form

- Hence the causalization of the equation system corresponds to a permutation of the structure-incidence matrix into lower-triangular form.
- A system in lower-triangular form can be solved by forward substitution.
- This is equivalent to a sequence of explicit computations and thus represents simple program code.
- Since the causality graph gives only rise to partial order, there might be more than one valid permutation.

## Block Lower Triangular Form

- Unfortunately, not all systems are permutable into lower-triangular form. (For instance: if the structure-incidence matrix is full, any permutation has no effect).

## Block Lower Triangular Form

- Unfortunately, not all systems are permutable into lower-triangular form. (For instance: if the structure-incidence matrix is full, any permutation has no effect).

This voltage potential cannot be explicitly determined, just by causalizing individual equations

## Block Lower Triangular Form

- Unfortunately, not all systems are permutable into lower-triangular form. (For instance: if the structure-incidence matrix is full, any permutation has no effect).
- So forward causalization is not a general procedure. It works only for very simple systems.
- If we cannot attain a lower-triangular form, we aim to be as close as possible to it. This is the block lower triangular (BLT) form.
- A matrix in BLT form is a matrix with blocks on the diagonal where the blocks are as small as possible.
- The blocks of a BLT form can be uniquely determined by the Dulmage-Mendelsohn Permutation.

# Dulmage-Mendelsohn Permutation III + 

In order to compute the block lower triangular form, we apply the Dulmage-Mendelsohn Permutation.

- This algorithm is combines a maximum matching on bipartite graphs with Tarjan`s strong component analysis.

|  | a | b | c | d | e | f | g | h |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| E1 | X | X |  |  |  |  |  |  |
| E2 |  | X |  | X |  |  |  |  |
| E3 |  | X | X |  |  |  |  |  |
| E4 |  |  | X | X | X | X |  |  |
| E5 |  | X |  |  | X |  |  |  |

| E7 |  |  |  |  |  | X | X | X |
| E8 |  |  |  |  | X |  | X | X |

## Bipartite Graphs

First let us look at the equation system in form of a bipartite graph.

- The first set of vertices is represented by the equations (E1-E8).
- The second set of vertices is represented by the variables (a-h).
- The occurrence of a variable $A$ in an equation $B$ represents an edge in the graph.

## Perfect Matching

In order to causalize the system, we need to assign an unknown to each equation.

- Such an assignments equals a perfect matching.
- A structural regular system contains at least one perfect matching.

## Bipartite Graphs

Given the graph $G(V, E)$ :

- A matching M in G consists in a set of edges $(\mathrm{M} \subseteq \mathrm{E})$ so that no vertex in G is connected to two edges in M .
- A maximal matching is a matching M so that no edge in $\mathrm{M} \backslash \mathrm{E}$ can be added.
- A maximum matching M is matching M so that there is no other matching $N$ for $G$ with $|N|>|M|$
- A perfect matching is a matching with no unmatched vertex in G .

## $\leftarrow$ matching

## Bipartite Graphs

Given the graph $G(V, E)$ :

- A matching M in G consists in a set of edges $(\mathrm{M} \subseteq \mathrm{E})$ so that no vertex in G is connected to two edges in M .
- A maximal matching is a matching M so that no edge in $\mathrm{M} \backslash \mathrm{E}$ can be added.
- A maximum matching M is matching M so that there is no other matching N for G with $|\mathrm{N}|>|\mathrm{M}|$
- A perfect matching is a matching with no unmatched vertex in G .

$\leftarrow$ maximal matching (can be obtained by a greedy algorithm)

## Bipartite Graphs

Given the graph $G(V, E)$ :

- A matching $M$ in $G$ consists in a set of edges $(M \subseteq E)$ so that no vertex in G is connected to two edges in M .
- A maximal matching is a matching M so that no edge in $\mathrm{M} \backslash \mathrm{E}$ can be added.
- A maximum matching M is matching M so that there is no other matching $N$ for $G$ with $|N|>|M|$
- A perfect matching is a matching with no unmatched vertex in G.

$\leftarrow$ maximum matching and perfect matching

## Perfect Matching

In order to causalize the system, we need to assign an unknown to each equation.

- Such an assignments equals a perfect matching.
- A structural regular system contains at least one perfect matching.

## Maximum Matching

Any perfect matching represents a maximum matching.

- For structurally singular systems, the maximum matching reveals the overconstrained equations and the undetermined variables.

Overconstrained Equation

Undetermined Variable

## Augmenting Paths

Getting a maximal matching is easy but how can we obtain a maximum (and hopefully perfect) matching?

- A path in $G$ is called alternating path if its edges alternate between the sets $\mathrm{E} \backslash \mathrm{M}$ and M (starting and ending arbitrarily).
- An augmenting path is an alternating path whose end-vertices are unmatched.
- Finding an augmenting path naturally leads to a matching that is larger by one: we can flip the matched edges with the unmatched edges.

## Augmenting Paths

This observation leads to the Augmenting Path Algorithm:

1. Look for an augmenting path by a depth-first traversal of the edges.
2. Increase the matching by one.
3. Repeat until you cannot find any augmenting path anymore.

- Finding an augmenting path takes at maximum $\mathrm{O}(|\mathrm{E}|)$ time.
- At maximum |V|/2 augmenting paths can be found.
- Hence the overall complexity is $\mathrm{O}(|\mathrm{V}||\mathrm{E}|)$

## Symmetric difference

It is evident that finding an augmenting path leads to a larger matching but how can we be sure that finding none indicates a maximum matching?

- Let N be a maximum matching. Now let us look at the symmetric difference $D$ between $M$ and $N: D=(M \cup N) \backslash(M \cap N)$
- D has a special structure. Each vertex in D can be at most connected to two edges (one in $M$ and one $N$ ). Hence each component $C$ of $D$ is either:
- an isolated vertex,
- a circle of even length, or
- an alternating path (cycle free).
- If $|\mathrm{N}|>|\mathrm{M}|$ then at least one component C must have an uneven number of edges. The only option is an augmenting path.
- We can make the stronger statement: For $k=|N|-|M|$ the symmetric difference $D$ contains $k$ disjoint augmenting paths.

## Algorithm of Hopcroft and Karp

This statement suggest an improvement of the augmenting path algorithm. Since the augmenting paths are disjoint, there cannot be many long augmenting paths.

1. Perform a breath-first search on $G$ to find the set of disjoint augmenting paths of minimal length.
2. Increase the matching for each augmenting path found
3. Repeat until no augmenting path can be found.

- Each breadth-first search takes $\mathrm{O}(|\mathrm{E}|)$ time.
- After $r=s q r t(|V|)$ steps, the minimum length of an augmenting path is $r$. There cannot be more than $|V| / r=r$ augmenting paths left. Hence the algorithm computes in $\mathrm{O}(\mathrm{r}=\mathrm{sqrt}(|\mathrm{V}|)|\mathrm{E}|)$
- This variant is called Hopcroft's Algorithm. (or Alg. of Hopcroft and Karp)

## Construction a Digraph

- The perfect matching assigns an unknown to each equation.
- This can be interpreted as a preliminary causalization of the equations.
- Hence, we can construct a causality graph.

## Construction a Digraph

Robotics and Mechatronics Centre

- The perfect matching assigns an unknown to each equation.
- This can be interpreted as a preliminary causalization of the equations.
- Hence, we can again construct a causality graph.

## Construction a Digraph

Robotics and Mechatronics Centre

- The perfect matching assigns an unknown to each equation.
- This can be interpreted as a preliminary causalization of the equations.
- Hence, we can again construct a causality graph.

## Strong Components

- But, now the causality graph is not acyclic anymore.
- The graph contains strong components

A strong component $H$ in a directed graph $G$ is a vertex-induced sub-graph of $G$ so that there is a path from each vertex to any other vertex in H .

- The strong components in the digraph represent the blocks in the BLTform of the structure-incidence matrix.

## Tarjan`s Algorithm

- Tarjan's strong component analysis is a depth-first traversal of the digraph with marking and backtracking.
- Idea:
- We traverse all vertices in depth-first manner.
- Each vertex is marked by an index i that represents the traversal number.
- A vertex that has been marked is not traversed again. So each vertex is only traversed only once.
- While backtracking, each vertex is assigned $j$ being the minimum index i or j of its direct neighbors (in the traversal stack) or of itself.
- Finally, each strong component has one root vertex where $\mathrm{i}=\mathrm{j}$.
- For those vertices where $\mathrm{i} \neq \mathrm{j}$, j points (directly or indirectly) to the root vertex of the strong component.

## Tarjan`s Algorithm: Example

- Here, we enumerate one possible depth first traversal.

## Tarjan`s Algorithm: Example

- Here, we enumerate the depth first traversal.

- While Backtracking, we reassign the minimum traversal number by the one of the vertex itself or its direct neighbors.

## Tarjan`s Algorithm: Example

## Tarjan`s Algorithm: Example

Robotics and Mechatronics Centre

- Let's do it step by step: Back-Tracking

## Tarjan`s Algorithm: Example

- Here, we enumerate one possible depth first traversal.

- While backtracking, we reassign the minimum traversal number by the one of the vertex itself or of those direct neighbors located on the traversal path.
- We find four strong components (where two are realocomponents)er 2014, slide 63

## Tarjan`s Algorithm: Watch it! (1)

- Here, a slight extension to the graph:

- E2, E3, E4, E5, E9 and E10 belong to one strong component.
- However, E10 and E9 point only indirectly to the root. E6 serves as a relay.

## Tarjan`s Algorithm: Watch it! (2)

- It is important that only neighbors on the traversal path are considered...

- ...because otherwise the components would be merged if we choose a different order of the depth-first traversal.

## Tarjan`s Algorithm: Complexity

- For the traversal, we traverse each vertex and each edge exactly once.

- So the algorithmic complexity is $\mathrm{O}(\mathrm{V}+\mathrm{E})$ or $\mathrm{O}\left(\mathrm{V}^{2}\right)$
- The maximum memory overhead is in $\mathrm{O}(\mathrm{V})$

## Tarjan`s Algorithm: Partial Order

- If we represent the strong components as a single vertex...

- ... the causality graph is again acyclic and gives rise to a partial order.
- (E6) -> (E4,E2,E3,E5) -> (E1) -> (E7,E8)
- This order can be used to create the BLT-form.

## Determining the BLT-Form

- If we represent the strong components as a single vertex...

|  | e | d | b | c | f | a | g | h |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| E6 | X |  |  |  |  |  |  |  |
| E4 | X | X |  | X | X |  |  |  |
| E2 |  | X | X |  |  |  |  |  |
| E3 |  |  | X | X |  |  |  |  |
| E5 |  |  | X |  | X |  |  |  |
| E1 |  |  | X |  |  | X |  |  |
| E7 |  |  |  |  |  |  | X | X |
| E8 |  |  |  |  | X |  | X | X |

- ... the causality graph is again acyclic and gives rise to a partial order.
- (E6) -> (E4,E2,E3,E5) -> (E1) -> (E7,E8)
- This order can be used to create the BLT-form.
- We have managed so far to isolate the blocks...
- ...but we still do not know how to generate code for the blocks.
- Idea: For each block we assume a set of its variables to be known. These are called tearing variables.
- Given this presumption, we can causalize all equations in the block.
- Some equations are overconstrained. These are turned into residual equations.
- So we do not generate code for the direct solution, but for an iterative numerical solver!

## Tearing

- Let us look at an example:
- E7: $\quad g+h=1 \quad(g, h$ are unknowns)
- E8: $\quad g^{*} h=f(f$ is known)
- We assume $g$ to be known. $g$ is a tearing variable. Now, we can causalize:
- E7: $h:=1-g$
- E8: residual $:=f-g^{*} h$
- For every value of $h$, we get a residual value in return. If $h$ is the correct solution the residual will be zero.
- The causalized block, now represents a function residual $=f(h)$. We can use this code in order to solve the system iteratively.

## Newton's Method

- In order to solve $0=\mathrm{f}(\mathrm{x})$, we can apply standard root-solving methods.
- The most prominent is Newton's Method.
- Newton's Method is an iterative algorithm and requires an initial guess $x:=x 0$
do

$$
\begin{aligned}
& y \quad:=f(x) \\
& x \_o l d \quad:=x ; \\
& x:=x-y /(d f(x) / d x) ; \\
& \text { while } 2^{*}\left|x \_o l d-x\right| /\left(\left|x \_o l d\right|+|x|\right)>\text { tol }
\end{aligned}
$$

## Newton's Method

Robotics and Mechatronics Centre

- In order to solve $0=\mathrm{f}(\mathrm{x})$, we can apply standard root-solving methods.
- The most prominent is Newton's Method:

## Newton's Method: Convergence

- Newton Converges with order 2.
- This means that within the convergence area, the number of correct digits doubles per step.
- For linear systems of equations, Newton converges in a single step.

## Newton's Method: MultiDim

- Newton's Method can be extended to the multi-dimensional case $r=f(x)$ where $r$ and $x$ are vectors of size $n$.
- To this end, we need to compute the Jacobian: $\mathbf{J}=\operatorname{Df}(\mathbf{x})$ Example for $\mathrm{n}=3$ :

$$
J=\left[\begin{array}{lll}
\partial f(x)_{1} / \partial x_{1} & \partial f(x)_{1} / \partial x_{2} & \partial f(x)_{1} / \partial x_{3} \\
\partial f(x)_{2} / \partial x_{1} & \partial f(x)_{2} / \partial x_{2} & \partial f(x)_{2} / \partial x_{3} \\
\partial f(x)_{3} / \partial x_{1} & \partial f(x)_{3} / \partial x_{2} & \partial f(x)_{3} / \partial x_{3}
\end{array}\right]
$$

- Iteration formula: $\mathbf{x}_{\text {new }}=\mathbf{x}-\Delta \mathbf{x}$
- Increment: $J \Delta \mathbf{x}=f(\mathbf{x})$
- In order to compute the increment, we need to solve a linear system of equations. This is of effort $\mathrm{O}\left(n^{3}\right)$

## Secant Method

- Newton requires the computation of the (partial) derivatives within the Jacobian Matrix.
- When these derivatives cannot be computed, we can take use of methods that approximate the derivates during the process of convergence.
- One example is the Secant Method:

## Selection of Tearing Variables

- There is one open question: How do we select the tearing-variables?
- Let us look at an example:
- E2:
$e=c+d+f$
(e is known)
E3: $b=d$
E4: $\quad \mathrm{c}=d$
E5: $\quad b=f$
- If we select $c$ and $b$ as tearing variables, we get two residuals:

E2: $f:=e-c-d$
E3: $d:=b$
E4: residual1 := $c-d$
E5: residual2 := b-f

## Selection of Tearing Variables

- There is one open question: How do we select the tearing-variables?
- Let us look at an example:
- E2:
$e=c+d+f$
(e is known)
E3: $b=d$
E4: $\mathrm{c}=d$
E5: $\quad b=f$
- But selecting $d$ as tearing variable, turns out to be sufficient:

E3: $b:=d$
E4: $c:=d$
E5: $f:=b$
E2: residual := $c+d+f-e$

## Selection of Tearing Variables

- By choosing a good set of tearing variables, we try to minimize the number of required tearing variables and residuals.
- This minimizes the effort of each Newton iteration and minimizes the amount of code that needs to be generated.
- Technically, we want to minimize the number of rows in the BLT-form that have non-zero entries above the diagonal.
- Unfortunately, this optimization problem is NP-hard.
- Hence, heuristics are applied. (For instance, choose the equation that has the lowest number of unknowns. From this equation, pick the variable that occurs in most other equations.)

## Some Remarks on Tearing

- Some remarks: Applying an iterative solver on tearing variables is just one of many methods to solve a system of non-linear equations.
- For band-matrices, tearing might be very tempting, since only a very small number of tearing variables is sufficient. But frequently, it is numerically highly unstable.
- In addition to tearing, Dymola transforms small linear systems into explicit form by symbolic manipulations.

## Some Remarks on Blocks

- So far, we looked at the BLT-Transformation from a purely structural viewpoint, assuming an equation can be solved for all its variables.
- In reality this is too simple. Let us consider:

$$
\mathrm{a}=\sin (\varphi)
$$

- By all means, we want to avoid causalizing for phi:

- Since this just picks one out of infinitely many solutions and might introduce discontinuities, when $\varphi$ crosses $n \cdot \pi$ during simulation time.

## Some Remarks on Blocks

- Usually, one solves an equation only for those variables that are linear extractable. This means that $x$ is only part of linear terms.
- Hence in reality, there might be more blocks than necessary from a pure structural viewpoint.
- One can also apply the tearing first and identify the blocks later. However, also this procedure may introduce extra blocks.
- Blocks are not nested!

## Summary

- The goal is to bring the flat system of DAEs into a form suited for numerical ODE solvers.
- To this end, the BLT-form is desired.
- The blocks can be identified using the Dulmage-Mendelsohn Permutation
- Perfect Matching
- Tarjan's Algorithm
- The individual Blocks are solved iteratively by using the tearing method.

## Questions?
